

jordans lemma

jordans lemma is a fundamental result in complex analysis and harmonic analysis, playing a crucial role in evaluating certain types of improper integrals using contour integration. This lemma provides a powerful tool for handling integrals involving oscillatory functions, particularly those with exponential terms. Understanding Jordans lemma is essential for mathematicians and engineers dealing with Fourier transforms, Laplace transforms, and analytic continuation. The lemma helps justify the vanishing of integrals over large semicircular contours in the complex plane, which in turn simplifies the application of the residue theorem. This article explores the statement of Jordans lemma, its proof, practical applications, and connections to other key concepts in analysis. The following sections will provide a comprehensive insight into the lemma's significance and utility in advanced mathematics.

Statement and Explanation of Jordans Lemma

Jordans lemma is primarily concerned with bounding contour integrals of functions multiplied by exponential terms of the form e^{izt} , where z is a complex variable and t is a positive real parameter. It states conditions under which the integral of such functions over a large semicircular arc in the complex plane tends to zero as the radius of the arc approaches infinity. This result is crucial for justifying the deformation of contours in the application of the residue theorem in complex analysis.

Formal Statement

Let $f(z)$ be a complex-valued function that is continuous on a semicircle of radius R in the upper half-plane and satisfies the inequality $|f(z)| \leq M(R)$ for some non-negative function $M(R)$. If $t > 0$, then the integral

$$\int_{C_R} f(z) e^{izt} dz$$

over the semicircular path C_R centered at the origin with radius R in the

upper half-plane tends to zero as $R \rightarrow \infty$, provided that $M(R)$ does not grow faster than a polynomial in R . In other words, the exponential term e^{izt} decays sufficiently fast on the semicircle to force the integral to vanish.

Intuitive Explanation

The key insight of Jordans lemma lies in the behavior of the exponential factor e^{izt} on the semicircle in the complex plane. When the path is chosen in the upper half-plane and t is positive, the imaginary part of z is positive, causing the exponential term to decay exponentially. This decay dominates any polynomial growth of $f(z)$, causing the integral over the large arc to approach zero as the radius increases. This allows the contour integral to be effectively reduced to the integral over the real axis plus residues at poles inside the contour.

Proof of Jordans Lemma

The proof of Jordans lemma involves estimating the magnitude of the contour integral over the semicircular arc by using the parametrization of the arc and bounding the integrand. The exponential decay in the integrand is exploited to show that the integral tends to zero as the radius grows without bound.

Setup and Parametrization

Consider the semicircle C_R parameterized by $z = Re^{i\theta}$ for $\theta \in [0, \pi]$. The integral over this path is

$$\int_0^\pi f(Re^{i\theta}) e^{iR e^{i\theta} t} i R e^{i\theta} d\theta$$

where $i R e^{i\theta} d\theta$ is the differential dz along the contour.

Bounding the Integral

Using the triangle inequality, the magnitude of the integral satisfies

$$\left| \int_{C_R} f(z) e^{izt} dz \right| \leq \int_0^\pi |f(Re^{i\theta})| |e^{iR e^{i\theta} t}| R d\theta$$

Since $|f(z)| \leq M(R)$, this further bounds the integral by

$$M(R) R \int_0^\pi |e^{iR e^{i\theta} t}| d\theta$$

Exponential Decay Analysis

Note that

$$|e^{iR e^{i\theta} t}| = e^{-R t \sin \theta}$$

because the real part of $i R e^{i\theta} t$ equals $-R t \sin \theta$. Since $\sin \theta \geq 0$ for $\theta \in [0, \pi]$, the exponential term decays exponentially except near $\theta = 0$ and $\theta = \pi$.

Estimating the Integral as $R \rightarrow \infty$

By splitting the integral into regions near $\theta = 0$ and $\theta = \pi$ where $\sin \theta$ is small, and the remainder where $\sin \theta$ is bounded away from zero, it can be shown that the integral tends to zero as R grows, provided $M(R)$ grows slower than an exponential function of R . This completes the proof that the contour integral vanishes in the limit.

Applications of Jordans Lemma in Complex Analysis

Jordans lemma is widely used in evaluating improper integrals, especially those arising in Fourier analysis, Laplace transforms, and in solving differential equations. Its ability to justify neglecting integrals over large arcs in the complex plane simplifies the use of contour integration methods significantly.

Residue Theorem and Contour Integration

The lemma enables the application of the residue theorem by allowing contours to be closed in the upper or lower half-plane without contributing integral from the large semicircle. This is particularly useful when dealing with integrals involving oscillatory functions multiplied by rational functions.

Fourier Transform Inversion

In Fourier analysis, Jordans lemma helps prove inversion formulas by ensuring that integrals over infinite semicircles vanish, which allows the integral representation of the inverse transform to be expressed as an integral over the real axis. This is essential in signal processing and systems theory.

Laplace Transform and Bromwich Integral

When inverting Laplace transforms using contour integrals (the Bromwich integral), Jordans lemma assists in justifying the closure of the contour in the right half-plane and the omission of the semicircular arc integral, facilitating the evaluation of inverse transforms.

Examples Illustrating Jordans Lemma

Several classical integral evaluations serve as examples of Jordans lemma in action. These examples highlight the utility of the lemma in simplifying and solving integrals that would otherwise be challenging.

Example: Integral of $\sin(x)/x$

Consider the integral

$$\int_{-\infty}^{\infty} (\sin x)/x \, dx$$

This integral can be evaluated using contour integration and Jordan's lemma by considering the function $f(z) = e^{iz}/z$ and integrating over a semicircular contour in the upper half-plane. The lemma ensures the integral over the arc vanishes, enabling the calculation of the principal value of the integral.

Example: Exponential Integral

Integrals of the form

$$\int_{-\infty}^{\infty} e^{ixt} / (x - a) \, dx$$

for real a and $t > 0$ can be evaluated by closing the contour in the upper half-plane and applying Jordans lemma to dismiss the contribution from the semicircle. This yields results involving the residue at $x = a$.

Summary of Steps in Example Applications

- Identify the function and the exponential factor with positive t .
- Choose an appropriate semicircular contour in the complex plane.
- Apply Jordans lemma to show the integral over the arc vanishes as radius $\rightarrow \infty$.
- Use the residue theorem to evaluate the integral over the closed contour.
- Interpret the result in terms of the original integral.

Related Concepts and Extensions

Jordans lemma is related to several other important concepts in complex and harmonic analysis, and there are generalizations that extend its

applicability.

Connection to the Riemann–Lebesgue Lemma

While Jordans lemma is concerned with contour integrals in the complex plane, the Riemann–Lebesgue lemma addresses the decay of Fourier transforms of integrable functions. Both lemmas highlight the vanishing nature of integrals involving oscillatory functions under certain conditions.

Extensions to Other Contours and Functions

Generalizations of Jordans lemma consider integrals over different contours such as semicircles in the lower half-plane or sectors in the complex plane, and functions with more general growth conditions. These extensions broaden the lemma's usefulness in more complex integral evaluations.

Jordan's Lemma in Signal Processing

In signal processing and control theory, the lemma aids in the analysis of system responses by justifying integral manipulations in the frequency domain, particularly when dealing with Laplace and Fourier transforms of time-domain signals.

Frequently Asked Questions

What is Jordan's lemma in complex analysis?

Jordan's lemma is a result used in complex analysis to evaluate certain contour integrals. It provides an estimate that helps show that the integral over a semicircular arc in the complex plane tends to zero as the radius goes to infinity, under appropriate conditions on the integrand.

How is Jordan's lemma applied in evaluating real integrals?

Jordan's lemma is often applied when using the residue theorem to evaluate real integrals involving trigonometric functions. By extending the integral to a contour in the complex plane and showing the integral over the semicircular arc vanishes, the lemma allows the calculation of the original integral via residues.

What conditions must be met for Jordan's lemma to hold?

For Jordan's lemma to apply, the integrand typically must be of the form $f(z)e^{iaz}$ where a is a positive real number, and $f(z)$ should be bounded or sufficiently well-behaved on the semicircular contour to ensure the integral over the arc tends to zero as the radius goes to infinity.

Can Jordan's lemma be used for integrals involving sine and cosine functions?

Yes, Jordan's lemma is frequently used to evaluate integrals involving sine and cosine by expressing these functions in terms of complex exponentials and applying contour integration techniques.

What is the difference between Jordan's lemma and the Jordan curve theorem?

Jordan's lemma is a tool in complex analysis used to evaluate contour integrals, particularly involving exponential functions, while the Jordan curve theorem is a topological result stating that a simple closed curve in the plane separates the plane into an interior and exterior region. They are unrelated concepts despite the similarity in name.

Why is Jordan's lemma important in the use of the residue theorem?

Jordan's lemma is important because it justifies ignoring the integral over the large semicircular arc in contour integration when applying the residue theorem, ensuring that only the integral along the real axis and the residues inside the contour contribute to the value of the integral.
